- Component properties:
- Precise property data for ethylene, acetic acid, vinyl acetate, water, and by-products are integrated into the database

- Loading Components and Defining Streams

- Input all relevant chemical components with their respective properties
- Set initial conditions (temperature, pressure, composition) for each feed
- Establish the flow rates based on production targets

Modeling the Reaction: Reactor Design and Kinetics

- The reaction is exothermic; proper heat removal is critical
- Implement heat exchangers within the simulation to control reactor temperature
- Use temperature profiles to optimize conversion and selectivity

Separation and Purification Units

Vinyl acetate typically needs to be separated from unreacted materials and by-products:

- Distillation Columns:
 - Used to purify VAM from residual acetic acid, water, and other impurities
 - Multiple stages may be necessary depending on purity requirements
- Column design parameters:
 - Number of stages
 - Reflux ratios
 - Operating pressures and temperatures
- Absorbers and Extractors:
 - For removing residual impurities or recovering unreacted gases
- Recycle loops:
 - Unreacted ethylene and acetic acid are often recycled to improve efficiency

Energy Integration and Utility Optimization

Simulation allows detailed energy analysis:

- Heat integration: Using waste heat from exothermic reactions to preheat feeds
- Utilities: Accurate sizing of boilers, cooling towers, and heat exchangers
- Energy balances: Ensuring minimal energy consumption for cost-effectiveness
