Congenital dysplasia and dislocation of the hip i

Congenital Dysplasia and Dislocation of the Hip I

Congenital dysplasia and dislocation of the hip (CDH), often referred to as developmental dysplasia of the hip (DDH), is a condition present at birth where the hip joint has not developed properly. It encompasses a wide spectrum of abnormalities, from mild acetabular dysplasia to complete dislocation of the femoral head from the acetabulum. This condition is one of the most common congenital orthopedic disorders and, if diagnosed and managed early, the prognosis for normal hip

development is excellent. Delayed diagnosis or untreated cases can lead to chronic pain, gait abnormalities, osteoarthritis, and disability in adulthood.

This comprehensive guide aims to provide in-depth information about congenital dysplasia and dislocation of the hip, including its causes, risk factors, clinical presentation, diagnostic methods, management options, and long-term outcomes.

Understanding Congenital Dysplasia and Dislocation of the Hip

Definition and Terminology

Congenital dysplasia and dislocation of the hip refer to a spectrum of developmental anomalies involving the hip joint:

- Hip Dysplasia: Abnormal development of the acetabulum and femoral head, resulting in a shallow socket and potential instability.
- Hip Dislocation: Complete displacement of the femoral head out of the acetabulum.
- Subluxation: Partial dislocation with the femoral head partially displaced but still in contact with the acetabulum.

The term DDH is often used interchangeably, emphasizing the developmental nature of the condition rather than a purely congenital origin.

Embryology and Pathogenesis

The development of the hip joint begins in the first trimester of fetal life, with complete ossification occurring after birth. The key points include:

- Proper formation of the acetabulum and femoral head depends on genetic, mechanical, and environmental factors.
- Abnormal intrauterine positioning, such as breech presentation, may interfere with normal hip development.
- Ligamentous laxity and hormonal influences (e.g., maternal estrogen) can contribute to instability.

The pathogenesis involves abnormal development leading to a spectrum of abnormalities, from slight acetabular dysplasia to complete dislocation.

Etiology and Risk Factors

Understanding the causes and risk factors helps in early identification and prevention strategies.

Etiology

While the exact cause remains multifactorial, contributing factors include:

- Genetic predisposition
- Mechanical factors during fetal development
- Hormonal influences affecting ligament laxity

Risk Factors

The following factors increase the likelihood of developing DDH:

- **Family History:** A positive family history, especially among siblings or parents, increases risk.
- **Breech presentation:** Fetuses in breech position are more susceptible due to abnormal positioning in utero.
- **Female gender:** DDH is more common in female infants, possibly due to hormonal factors.
- **Firstborn status:** First pregnancies may involve tighter uterine muscles, impacting hip development.
- **Oligohydramnios:** Reduced amniotic fluid limits fetal movement, affecting joint development.
- **Swaddling practices:** Tight swaddling with hips in extension and adduction can increase risk.

Clinical Presentation

The presentation of DDH varies with age and severity. Recognizing early signs enables prompt intervention.

Neonatal and Infant Signs

In newborns and infants, signs may include:

- **Limited hip abduction:** Reduced movement when attempting to abduct the hip.
- **Asymmetry of thigh and gluteal folds:** Unequal skin folds or thigh lengths.
- **Barlow and Ortolani tests:** Physical maneuvers to detect instability or dislocation.
- **Galeazzi sign:** Unequal knee levels when hips and knees are flexed.
- **Positive Ortolani test:** Hearing a clunk when reducing a dislocated hip back into the socket.
- **Positive Barlow test:** Feeling a clunk when attempting to dislocate a partially unstable hip.

Older Children and Adolescents

Signs may include:

- **Gait abnormalities:** Limping or Trendelenburg gait.
- **Hip pain:** Especially after activity or in older patients.
- **Limited range of motion:** Particularly abduction and internal rotation.
- **Leg length discrepancy:** Affected limb may appear shorter.

Diagnostic Evaluation

Accurate diagnosis relies on a combination of physical examination and imaging studies.

Physical Examination

Key maneuvers and observations include:

- **Barlow test:** To detect hip instability by applying gentle posterior pressure while the hip is in flexion.
- **Ortolani test:** To confirm reducibility of a dislocated hip by gentle abduction while lifting the femoral head into the socket.
- **Galeazzi sign:** Comparing knee levels when hips and knees are flexed.
- **Range of motion assessment:** Particularly abduction and internal rotation limitations.

Imaging Studies

The choice of imaging depends on age and clinical suspicion:

- **Ultrasound:** The gold standard in infants under 6 months; evaluates femoral head position, acetabular coverage, and shape.
- **Anteroposterior (AP) pelvis X-ray:** Used in children over 4-6 months; assesses ossification centers, joint congruency, and acetabular index.
- **Other imaging:** MRI or CT scans may be used for complex cases or preoperative planning.

Key measurements include:

- Acetabular index

- Shenton's line
- Femoral head ossification center position

Management Strategies

Treatment depends on age at diagnosis, severity, and stability of the hip joint.

Non-Surgical Management

Primarily effective in infants younger than 6 months.

- **Pavlik harness:** The most commonly used device that maintains hips in flexion and abduction, promoting proper development.
- **Other orthoses:** Dynamic abduction braces or splints in select cases.

Key points for non-surgical treatment:

- Early initiation improves outcomes.
- Regular follow-up with clinical and ultrasound assessments.
- Duration typically ranges from 6 to 12 weeks.

Surgical Management

Indicated in older children, failed conservative treatment, or severe dislocations.

- **Closed reduction:** Under anesthesia, with or without pre-reduction traction, followed by spica casting.
- **Open reduction:** Surgical repositioning of the femoral head into the acetabulum, often combined with adjunct procedures.
- **Pelvic osteotomy:** To reshape or deepen the acetabulum, especially in older children with residual dysplasia.
- **Femoral osteotomy:** To correct deformity or improve joint stability.

Postoperative care involves immobilization in a cast and gradual return to activity, with ongoing monitoring through imaging.

Prognosis and Long-Term Outcomes

Early detection and treatment generally lead to excellent outcomes. However, delayed diagnosis can result in:

- Persistent joint instability
- Acetabular dysplasia
- Early osteoarthritis
- Gait disturbances
- Leg length discrepancy

Factors influencing prognosis include:

- Age at diagnosis
- Severity of dysplasia or dislocation
- Timeliness and adequacy of treatment
- Compliance with management protocols

Long-term follow-up into adulthood is essential to monitor for degenerative changes and functional limitations.

Prevention and Screening

Preventive strategies focus on early detection and avoiding modifiable risk factors.

Screening Programs

Many countries implement neonatal screening programs involving:

- Physical examination (Barlow, Ortolani, Galeazzi tests)
- Ultrasound screening in high-risk infants
- Parental education on hip health and positioning

Guidelines for Safe Swaddling

Promoting hip-healthy swaddling practices can reduce risk:

- Allow hips to remain flexed and abducted.
- Avoid tight wrapping around the hips in extension and adduction.

Conclusion

Congenital dysplasia and dislocation of the hip is a common but manageable condition when diagnosed early. Awareness of

Congenital Dysplasia and Dislocation of the Hip: An In-Depth Review

Congenital dysplasia and dislocation of the hip (CDH), also known as developmental dysplasia of the hip (DDH), represents a spectrum of hip joint abnormalities present at birth. These conditions encompass a range of morphological deviations, from mild acetabular dysplasia to complete femoral head dislocation. Despite advances in neonatal screening and early intervention strategies, CDH remains a significant cause of gait abnormalities, hip osteoarthritis, and disability if left untreated. This comprehensive review aims to elucidate the etiology, pathophysiology, clinical presentation, diagnosis, management, and prognosis of congenital dysplasia and dislocation of the hip, emphasizing current practices and future directions.

Understanding Congenital Dysplasia and Dislocation of the Hip

The term congenital dysplasia and dislocation of the hip describes a spectrum of developmental anomalies involving the hip joint. The condition is characterized by abnormal development of the acetabulum and femoral head, which may remain partially or completely dislocated.

Definitions and Terminology

- Congenital Hip Dysplasia (CHD): A general term denoting abnormal development of the hip joint, including shallow acetabulum, labral abnormalities, and subluxation.
- Developmental Dysplasia of the Hip (DDH): The preferred term in recent literature, reflecting the condition's developmental nature rather than purely congenital origin.
- Dislocation: Complete displacement of the femoral head out of the acetabulum.

Epidemiology

- Incidence varies globally, with estimates ranging from 1 to 34 per 1,000 live births.
- Higher prevalence in females (approximately 4-8 times more common than males).
- The left hip is more frequently affected, potentially due to intrauterine positioning.
- Risk factors include breech presentation, family history, swaddling practices, and ligamentous laxity.

Etiology and Pathogenesis

The etiology of CDH is multifactorial, involving genetic, environmental, and mechanical factors.

Genetic Factors

- Family history significantly increases risk, indicating hereditary predisposition.
- Multiple genes implicated include those involved in connective tissue integrity and joint development, such as TBOX1, PAX3, and GDF5.

Environmental and Mechanical Factors

- Intrauterine positioning, particularly breech presentation, exerts abnormal mechanical forces on the developing hip.
- Swaddling practices that keep hips extended and adducted may contribute.
- Oligohydramnios and intrauterine constraint can influence joint development.

Pathophysiology

The abnormal development begins with insufficient acetabular coverage of the femoral head, leading to:

- Shallow or oblique acetabulum.
- Ligamentous laxity allowing subluxation or dislocation.
- Altered biomechanics resulting in delayed ossification and joint instability.

Over time, persistent dysplasia can cause adaptive changes, including:

- Acetabular flattening.
- Femoral head deformity.
- Coxa valga and other deformities.

Clinical Presentation and Screening

Early detection of CDH is crucial for successful management. The presentation varies with age and severity.

Neonatal Period

- Often asymptomatic.
- Asymmetry of thigh or gluteal folds.
- Limited abduction on the affected side.
- A positive Ortolani test (clunk upon abduction indicating reducible dislocation).
- A positive Barlow test (dislocation when applying posterior force).

Infant and Toddler Period

- Persistent limitation of abduction.
- Limb length discrepancy.
- Positive Galeazzi sign (apparent limb length discrepancy when hips are flexed).

Older Children and Adolescents

- Trendelenburg gait.
- Hip pain or stiffness.
- Osteoarthritis signs.

Screening Strategies

- Universal screening: Physical examination of all newborns.
- Selective screening: Targeted for high-risk groups.
- Ultrasonography: The gold standard for infants under 4-6 months when the femoral head has not ossified.
- Radiography: Used after ossification of the femoral head (~4-6 months).

Ultrasound Evaluation

- Graf classification system assesses hip morphology based on alpha and beta angles.
- Types I-IV, with type I being normal and type IV indicating dislocation.

Diagnosis and Classification

Accurate classification guides management and prognosis.

Graf Classification

- Type I: Normal.
- Type II: Dysplastic but reducible.
- Type III: Subluxed.
- Type IV: Dislocated with no contact.

Other Classifications

- Harcke method (dynamic ultrasound).
- Terjesen method (alpha angle measurement).

Imaging Modalities

- Ultrasound: Preferred in infants under 6 months.
- Radiographs: For older infants and children, assessing acetabular index and femoral head position.

Key Measurements

- Acetabular index: Angle of acetabular roof; normal varies with age.
- Shenton's line: Smooth arc indicating congruent hip.
- Femoral head ossification center: Presence and position.

Management Approaches

The goal of treatment is to ensure concentric reduction of the femoral head within the acetabulum, promoting normal development.

Non-operative Management

Pavlik Harness

- First-line treatment for infants aged 0-6 months.
- Maintains hip flexion and abduction.
- Success rate exceeds 90% when applied early.
- Monitoring for complications like femoral nerve palsy or avascular necrosis (AVN).

Other Devices

- Abduction braces or orthoses.
- Closed reduction with casting in some cases.

Observation

- Mild dysplasia may resolve spontaneously, especially with normal ultrasound findings.

Surgical Management

Indications include failed conservative therapy, late diagnosis, or irreducible dislocation.

Procedures

- Closed reduction and casting: Typically performed in infants over 6 months.
- Open reduction: For irreducible dislocations or persistent dysplasia.
- Pelvic osteotomies: To correct acetabular dysplasia, including Salter, Pemberton, or Dega osteotomies.
- Femoral osteotomies: To correct deformities like coxa valga.

Timing

- Early intervention (before walking age) yields better outcomes.
- Delayed treatment increases the risk of osteoarthritis and functional impairment.

Prognosis and Long-term Outcomes

The prognosis hinges on the age at diagnosis, severity, and treatment adequacy.

Factors Influencing Outcomes

- Early detection (preferably before 6 months).
- Complete and stable reduction.
- Adequate acetabular development.

Potential Complications

- Avascular necrosis of the femoral head.
- Residual dysplasia.
- Re-dislocation.
- Osteoarthritis in later life.

Long-term Follow-up

- Regular clinical and radiographic assessments.
- Monitoring for signs of osteoarthritis or gait abnormalities.

Future Directions

- Improved screening protocols.
- Genetic studies to identify at-risk populations.
- Development of minimally invasive surgical techniques.
- Use of 3D imaging and modeling for surgical planning.
- Innovative biological therapies to enhance cartilage and bone regeneration.

Conclusion

Congenital dysplasia and dislocation of the hip remains a significant orthopedic challenge worldwide. Early detection through vigilant neonatal screening and prompt intervention can dramatically improve outcomes, preventing long-term disability. A multidisciplinary approach encompassing orthopedic surgeons, radiologists, physiotherapists, and pediatricians is vital to optimize care. Advances in imaging, surgical techniques, and understanding of genetic factors promise continued improvements in management strategies. As research progresses, the goal remains to minimize the physical and psychological burden of this condition, ensuring better quality of life for affected individuals.

Question What is congenital dysplasia and dislocation of the hip? Congenital dysplasia and dislocation of the hip (CDH) is a condition present at birth where the hip joint is improperly formed, leading to instability or dislocation of the femoral head from the acetabulum. What are the common risk factors for congenital hip dysplasia? Risk factors include breech presentation, family history of hip dysplasia, female sex, first pregnancy, oligohydramnios, and certain genetic conditions. How is congenital hip dysplasia diagnosed in infants? Diagnosis typically involves

physical examination maneuvers such as Ortolani and Barlow tests, followed by imaging studies like ultrasound in infants under 6 months and X-rays in older infants and children. What are the clinical signs of congenital hip dislocation in newborns? Signs include limited hip abduction, a positive Ortolani or Barlow test, asymmetric thigh or gluteal folds, and an apparent leg length discrepancy. What is the standard treatment for congenital hip dysplasia in newborns? Early treatment usually involves Pavlik harness orthosis to maintain the hip in proper alignment, which can often correct the dysplasia if initiated promptly. When is surgical intervention indicated for congenital hip dislocation? Surgery is considered if conservative methods fail or if diagnosis occurs after the neonatal period, typically involving closed or open reduction, osteotomies, or other procedures depending on severity. What are the potential long-term complications of untreated congenital hip dysplasia? Untreated dysplasia can lead to early osteoarthritis, limping, hip pain, gait abnormalities, and functional impairment in adulthood. How can congenital hip dysplasia be prevented or detected early? Universal screening with physical exams during neonatal visits and early use of ultrasound in at-risk infants facilitate early detection and management to prevent complications. What is the prognosis for children treated for congenital hip dysplasia?
