In-Depth Review of Key Concepts with Answers

1. Calculating Heat Transfer in Calorimetry

Question:

A 50.0 g sample of water is heated from 25°C to 75°C. How much heat energy is absorbed?
(Specific heat capacity of water = 4.18 J/g°C)

Answer:

Using the formula:

$$q = mc\Delta T$$

where:

- $m = 50.0\text{ g}$
- $c = 4.18\text{ J/g}^\circ\text{C}$
- $\Delta T = 75^\circ\text{C} - 25^\circ\text{C} = 50^\circ\text{C}$

Calculation:

$$q = 50.0\text{ g} \times 4.18\text{ J/g}^\circ\text{C} \times 50^\circ\text{C}$$

$$q = 50.0 \times 4.18 \times 50 = 10,450\text{ J}$$

Result:

The water absorbs 10,450 Joules of heat energy.

2. Applying Hess's Law

Question:

Given the following reactions:

- $\text{C} + \text{O}_2 \rightarrow \text{CO}_2$ ($\Delta H = -393.5 \text{ kJ}$)
- $\text{CO} + \frac{1}{2} \text{O}_2 \rightarrow \text{CO}_2$ ($\Delta H = -283 \text{ kJ}$)

Find ΔH for the reaction:

Answer:

Using Hess's Law, arrange the reactions to cancel out common terms:

From the second reaction:

Reversing it:

Now, add this to the first reaction:

Sum:

Simplify:

Total enthalpy change:

$$(-393.5 \text{ kJ} + 283 \text{ kJ} = -110.5 \text{ kJ})$$

Result:

$\Delta H = -110.5 \text{ kJ}$ for the formation of CO from C and O_2 .

3. Bond Enthalpy Calculations

Question:

Calculate the approximate enthalpy change for the reaction:

$\text{CH}_4 + 2 \text{O}_2 \rightarrow \text{CO}_2 + 2 \text{H}_2\text{O}$, using bond enthalpies provided:

| Bond | Enthalpy (kJ/mol) |

|-----|-----|

| C-H | 412 |

| C=O | 799 |

| O=O | 498 |

Answer:

Step 1: Break all bonds in reactants:

- 4 C-H bonds: $(4 \times 412 = 1648 \text{ kJ})$

- 2 O=O bonds: $(2 \times 498 = 996 \text{ kJ})$

Total energy to break bonds: $(1648 + 996 = 2644 \text{ kJ})$

Step 2: Form bonds in products:

- 2 C=O bonds in CO_2 : $(2 \times 799 = 1598 \text{ kJ})$

- 4 O-H bonds in 2 H_2O molecules: $(4 \times 463 = 1852 \text{ kJ})$ (assuming O-H bond enthalpy is 463 kJ/mol)

Total energy released: $(1598 + 1852 = 3450 \text{ kJ})$

Step 3: Calculate ΔH :

$\Delta H \approx \text{Energy to break} - \text{Energy to form} = 2644 - 3450 = -805 \text{ kJ}$

Result:

Approximate enthalpy change for the reaction is -805 kJ (exothermic).

QuestionAnswer What is the main concept behind thermochemistry in Pearson Chemistry? Thermochemistry focuses on the study of heat changes that occur during chemical reactions and physical processes, emphasizing concepts like enthalpy, heat capacity, and calorimetry. How do you

calculate the enthalpy change for a reaction using Hess's Law? You add or subtract the known enthalpy changes of related reactions to find the overall enthalpy change for the target reaction, ensuring the reactions are combined appropriately to cancel out intermediates. What methods are commonly used to measure heat transfer in thermochemistry experiments? Calorimetry, particularly coffee cup and bomb calorimetry, are commonly used to measure heat transfer during chemical reactions by monitoring temperature changes in a controlled environment. How does bond enthalpy relate to the energy changes observed in thermochemistry? Bond enthalpy represents the energy required to break a specific bond in a molecule; differences in bond enthalpies between reactants and products help determine the overall enthalpy change of the reaction. What is the significance of standard enthalpy of formation in thermochemical calculations? Standard enthalpy of formation is the heat change when one mole of a compound forms from its elements in their standard states, serving as a reference point for calculating reaction enthalpies. How do endothermic and exothermic reactions differ in thermochemical terms? Endothermic reactions absorb heat from their surroundings, resulting in a positive enthalpy change, while exothermic reactions release heat, leading to a negative enthalpy change. What role does heat capacity play in calorimetry experiments? Heat capacity indicates how much heat is needed to raise the temperature of a substance by a certain amount; it's essential for calculating the heat transferred during reactions in calorimetry. How can you determine the enthalpy change of a reaction experimentally using calorimetry? By measuring the temperature change of a known quantity of reactants or products in a calorimeter and applying the heat capacity, you can calculate the heat transferred and thus the enthalpy change. Why is it important to consider the state (pressure, temperature) when discussing thermochemical data? Thermochemical data are state functions; the enthalpy change depends on the initial and final states. Consistency in pressure and temperature conditions ensures accurate and comparable measurements.

As part of comprehensive chemistry education, mastering thermochemistry not only enhances academic

performance but also provides insights into real-world applications such as energy production, environmental science, and engineering.

In this article, we will explore the core topics covered in thermochemistry, analyze common review questions and their answers, and provide effective strategies for studying this critical section of chemistry.

Overview of Thermochemistry

Thermochemistry is a branch of thermodynamics focused on the study of heat changes during chemical reactions and physical processes. It involves understanding how energy is absorbed or released, quantifying these changes, and applying thermodynamic principles to analyze systems.

Key Concepts in Thermochemistry

- Endothermic and Exothermic Reactions: Reactions that absorb heat (endothermic) versus those that release heat (exothermic).
- Enthalpy (ΔH): A measure of the total heat content of a system at constant pressure.
- Heat Capacity and Specific Heat: The amount of heat needed to change the temperature of a substance.
- Hess's Law: The total enthalpy change for a reaction is the same regardless of the pathway taken.
- Calorimetry: The experimental technique used to measure heat changes in chemical reactions.

Common Review Questions and Their Answers

Studying thermochemistry involves tackling a variety of questions that test conceptual understanding and calculation skills. Here are some typical review questions along with detailed answers.

1. What is the difference between heat and temperature?

- Answer:

Heat refers to the transfer of thermal energy between systems due to a temperature difference and is measured in joules (J) or calories. Temperature, on the other hand, is a measure of the average kinetic energy of particles in a substance, expressed in degrees Celsius, Kelvin, or Fahrenheit. While heat involves energy transfer, temperature is a state function indicating thermal intensity.

2. How do you calculate the heat absorbed or released in a physical or chemical

process?

- Answer:

The heat (q) can be calculated using the formula:

$$q = mc\Delta T$$

$$q = mc\Delta T$$

where:

- m = mass of the substance
- c = specific heat capacity
- ΔT = change in temperature (final - initial)

For chemical reactions, enthalpy changes (ΔH) are often used, especially at constant pressure, and can be determined through calorimetry or Hess's Law.

3. What is Hess's Law, and how is it useful in thermochemistry?

- Answer:

Hess's Law states that the total enthalpy change for a reaction is the same, regardless of the number of steps or pathway taken, provided the initial and final states are the same. It is useful because it allows us to calculate enthalpy changes for reactions that are difficult to measure directly by combining known reactions with their enthalpy changes.

4. How do you determine the enthalpy change of a reaction using bond energies?

- Answer:

The enthalpy change can be estimated with bond energies as follows:

$$\Delta H = \sum \text{Bond Energies of bonds broken} - \sum \text{Bond Energies of bonds formed}$$

This involves summing the energy required to break bonds in the reactants and subtracting the energy released when new bonds form in the products.

5. What is calorimetry, and how is it used to measure heat transfer?

- Answer:

Calorimetry is an experimental technique used to measure the heat involved in chemical or physical processes. A calorimeter isolates the system from the surroundings and measures temperature changes caused by the process. The amount of heat transferred is calculated using the calorimeter's heat capacity and the observed temperature change.
